Hyperplanes as Point Sets Algebraic Definition

A hyperplane is defined as the set of points satisfying a linear equation:

$$f(x_1,...,x_d) = k_1 x_1 + \dots + k_d x_d + k_0 = 0, \quad k_i \in \mathbb{R}.$$
 (1)

Examples:

• Line:
$$\{(x_1, x_2) \mid 2x_1 - x_2 = 3\} \subset \mathbb{R}^2$$

- ▶ Plane: $\{(x_1, x_2, x_3) \mid x_1 + 2x_2 x_3 = -1\} \subset \mathbb{R}^3$
- ▶ Hyperplane: $\{(x_1, x_2, x_3, x_4) \mid x_1 + 2x_2 x_3 + 5x_4 = 1\} \subset \mathbb{R}^4$

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Hyperplanes as Point Sets

Gradient Representation

Equivalently, a hyperplane can be described using the normal vector v and distance k/||v|| from the origin:

$$f = v \cdot (x_1, \ldots, x_d) + k_0. \tag{2}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Properties:

- If $k_0 = 0$, the hyperplane passes through the origin.
- Example: $v = (2, -1), k_0 = -3 \Rightarrow f = 2x_1 x_2 3$
- For $f(x_1,...,x_d) = k_1x_1 + \cdots + k_dx_d + k_0$:

$$\nabla f = \left(\frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, \dots, \frac{\partial f}{\partial x_d}\right) = (k_1, \dots, k_d) = v$$

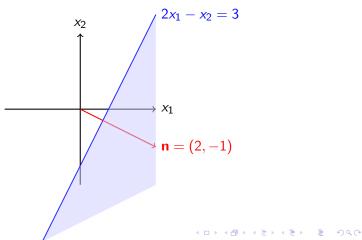

Halfspaces

A half-space is one side of a given hyperplane with dimension d.

$$\{(x_1,\ldots,x_d) \mid f(x_1,\ldots,x_d) \gtrsim 0\}.$$
 (3)

Examples:

• Half-plane: $\{(x_1, x_2) \mid 2x_1 - x_2 > 3\} \subset \mathbb{R}^2$

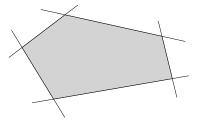

Convex Polytope (Definition 1)

as Intersection of Half-Spaces

- A convex polytope (polyhedron) is the intersection of a finite number of half-spaces.
- Expanding the set of half-spaces reduces or maintains the intersection size.
- Example: Any d = 2 convex polytope can be expressed as an intersection of half-planes.

イロト 不得 トイヨト イヨト

Convex Polytope (Definition 2)

Representation via Convex Combinations

Given points $A_1, \ldots, A_n \in \mathbb{R}^d$, the convex hull $CH(A_1, \ldots, A_n)$ is the smallest convex polytope containing these points.

- The vertices of *CH* belong to $\{A_1, \ldots, A_n\}$.
- Points in CH are convex combinations:

$$\lambda_1 P_1 + \dots + \lambda_k P_k, \quad \sum \lambda_i = 1, \lambda_i \ge 0.$$
 (4)

Carathéodory's Theorem: Any point in CH is a convex combination of at most d + 1 vertices.

Supporting Hyperplanes

Faces, Edges, and Facets

A supporting hyperplane of a polyhedron P intersects P but does not divide it into separate parts.

Face of polytope P is the intersection of a sup. hyperplane with P.

Common Faces:

- Vertex: 0-dimensional face.
- **Edge**: 1-dimensional face.
- **Facet**: (d-1)-dimensional face.
- **Ridge**: (d-2)-dimensional face.
- A *d*-dimensional polyhedron is considered a face of dimension *d*.

• The empty set \emptyset is a face of dimension -1.

Supporting Hyperplanes (Revisited)

Supporting Hyperplanes of Faces

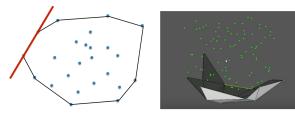

- Each facet has a unique supporting hyperplane, while other faces have infinitely many.
- For k = 0 (vertex), the set of supporting hyperplanes has dimension:
 - 1 in the plane (eliminates one angle),
 - 2 in three-dimensional space (eliminates two angles),
 - ▶ d − 1 in general.

2D

• The set of supporting hyperplanes of a k-face has dimension d - k - 1.

Types of Polytopes

- Simplex: A polytope with d + 1 affinely independent vertices.
- Simple Polytopes: Every vertex belongs to exactly *d* facets.
- Simplicial Polytopes: Each facet is a simplex.

Simplices

Definition

d-**Simplex**: A convex polyhedron $CH(A_0, \ldots, A_d)$ such that the points $A_i \in \mathbb{R}^d$ are affinely independent, meaning $A_i - A_0$ are linearly independent.

Lemma

Each simplex has:

- $d + 1 = \binom{d+1}{d}$ facets, each defined by d vertices.
- $\binom{d+1}{2}$ edges: each pair of vertices defines an edge.
- Each k + 1 vertices define a k-simplex with ^{d+1} _{k+1} faces of dimension k.

Types of Convex Polyhedra

Definition **Simple Polyhedron**: A convex polyhedron where exactly d facets meet at each vertex.

Definition

Simplicial Polyhedron: A convex polyhedron where every facet is a simplex of dimension d - 1.

Lemma (Exercise)

- ▶ In the plane, every polygon is both simple and simplicial.
- The only simple and simplicial polyhedron in dimensions ≥ 3 is the simplex.
- Any polyhedron can be made simplicial by triangulating its facets.
- Find a i) simple (not simplicial) polytope, ii) simplicial (not simple) polytope, iii) not simple neither simplicial polytope

Upper Bound Theorem

Theorem (McMullen)

Any d-dimensional polyhedron with n vertices (or n facets) contains:

$$O\left(n^{\lfloor d/2 \rfloor}\right) \tag{5}$$

k-dimensional faces, for dimensions $k = 0, \ldots, d - 1$.

Corollary

- d = 2: O(n) edges and vertices.
- d = 3: O(n) facets, edges, and vertices.
- d = 4: $O(n^2)$ facets and edges for n vertices.

Computational Complexity Results

Corollary

The worst-case computational complexity for computing the convex hull of n points in \mathbb{R}^d is:

$$\Omega(n\log n + n^{\lfloor d/2 \rfloor}) \tag{6}$$

Corollary

The storage complexity of the adjacency graph of a polyhedron is:

$$\Omega(n^{\lfloor d/2 \rfloor}) \tag{7}$$

Cyclic Polytopes

A cyclic polytope C_d(n) is the convex hull of n points on the moment curve in R^d:

$$(x_1, x_1^2, x_1^3, \ldots, x_1^d), \ldots, (x_n, x_n^2, x_n^3, \ldots, x_n^d)$$

where $x_1 < x_2 < \cdots < x_n$ are distinct real numbers.

Key properties:

- Maximal Simpliciality: Every facet is a simplex.
- Upper Bound Theorem: Achieves the maximal number of faces for given n and d.

• Neighborly Property: Any $\lfloor d/2 \rfloor$ vertices form a face.

Examples of Cyclic Polytopes

Low-dimensional cases:

- $C_2(n)$: Convex *n*-gon in \mathbb{R}^2 .
- $C_3(n)$: A 3D convex polyhedron with triangular faces.
- $C_4(n)$: A 4D polytope with tetrahedral facets.

Numerical examples:

- C₂(6): Convex hexagon in ℝ² with points (1, 1), (2, 4), (3, 9), (4, 16), (5, 25), (6, 36).
- C₃(6): A 3D convex polyhedron with points
 (1, 1, 1), (2, 4, 8), (3, 9, 27), (4, 16, 64), (5, 25, 125), (6, 36, 216).

 $C_2(6)$: Convex hexagon

Convex Hull Algorithms

Beneath-Beyond Algorithm in 3-dimensions

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Beneath-Beyond for dD Convex Hull Gift Wrapping algorithm

Beneath-Beyond Algorithm

General Framework

- 1. Given the convex hull of k points, insert a new point p.
- 2. Determine the position of *p* relative to the convex hull; ignore it if it is inside.
- 3. Otherwise, compute a *certificate* proving that *p* is an exterior point.
- 4. Use this certificate to update the convex hull (preserve part of the hull with *p*, remove another part).

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Incremental Algorithm for Convex Hull in 3D

Input: *n* points in \mathbb{R}^3 , in general position. Output: The convex hull (e.g., as an adjacency graph).

- 1. Sort points lexicographically by decreasing x_1 : p_1, \ldots, p_n .
- 2. Initialization: Start with a tetrahedron from the four rightmost points.
- 3. For p_k , k = 5, ..., n:
 - Check facets incident to p_{k-1} : Identify any red facet.
 - Identify all red facets and purple edges.
 - Remove red facets, edges, vertices from the hull.
 - Insert new facets (edges) defined by p_k and purple edges (vertices).

4. Return the updated convex hull.

Correctness of the Beneath-Beyond Algorithm

Lemma (Predicate)

For each facet of the current polyhedron, the following conditions are equivalent:

- ► The facet is either blue or red.
- ▶ The facet is not visible / visible from the new point.
- The new point lies in the same / different half-space relative to the supporting plane of the facet.
- The sign of the orientation predicate for the facet vertices with the new point is the same / different compared to that with any point inside the current polyhedron.

Orientation Predicate

Lemma

The orientation of four points $p_i = (x_i, y_i, z_i)$, i = 0, ..., 3 reduces to the sign of the determinant:

$$\det \begin{bmatrix} 1 & x_0 & y_0 & z_0 \\ 1 & x_1 & y_1 & z_1 \\ 1 & x_2 & y_2 & z_2 \\ 1 & x_3 & y_3 & z_3 \end{bmatrix}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

It is zero if and only if the four points are coplanar.

Complexity of the Beneath-Beyond Algorithm

Lemma

At each incremental step:

- The set of purple edges/vertices is topologically equivalent to a convex polygon.
- This polygon is a convex hull of at most n points, thus has size O(n).
- The set of new facets/edges corresponds one-to-one with the purple edges/vertices.

Overall Complexity for 3D Convex Hull Algorithm

- Initial sorting: $O(n \log n)$.
- Complexity depends on:
 - Total number of red facets/edges, bounded by the total number of constructed facets/edges O(n²).
 - Total number of red vertices $\leq n$.
 - Number of purple edges/vertices = O(n) per step.
 - Number of constructed facets/edges = O(n) per step.

• Overall complexity: $O(n^2)$.

Alternative: unsorted insertion, point location, randomized $O(n \log n)$

Generalization to Higher Dimensions

- New convex hull $C' = CH(C \cup \{p\})$.
- Facets of C split into two categories:

F = blue / red if p is in same / different half-space.

General position ensures p is not on a supporting hyperplane.

- Lower-dimensional faces split into:
 - Red: Intersection of only red facets.
 - Blue: Intersection of only blue facets.
 - Purple: Intersection of both red and blue facets.

Overall Complexity of Beneath-Beyond in dD

Theorem

Given n points in \mathbb{R}^d , the worst-case time complexity for constructing the convex hull is:

$$O(n \log n + n^{\lfloor (d+1)/2 \rfloor})$$

which is optimal only for even dimensions.

Theorem (Seidel)

Using randomized techniques, an expected time complexity of $O(n \log n + n^{\lfloor d/2 \rfloor})$ can be achieved.

Theorem (Chazell)

A more complicated deterministic version has time complexity of $O(n \log n + n^{\lfloor d/2 \rfloor})$ (worst-case optimal).

Gift Wrapping Approach

- n points in general position in ℝ^d: every d points define a hyperplane, and no d + 1 points lie on the same hyperplane.
- Data structure RACH stores known ridges for examination (one adjacent facet is known).
- Ridges are stored as $(F \{x\}, x)$ where:
 - F is the set of points defining a facet containing the ridge.

x is the vertex of the facet not in the ridge.

Function FIND-OTHER-FACET

Input: Ridge R and vertex $c \notin R$, where $R \cup \{c\}$ forms a facet of the convex hull.

Output: A facet of the convex hull containing R and different from $R \cup \{c\}$.

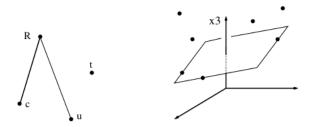

- 1. Select candidate point u not in $R \cup \{c\}$.
- 2. For each $t \notin R \cup \{c, u\}$:
 - If c and t are in different half-spaces relative to the hyperplane of R ∪ {u}, then update u ← t.

3. Return facet $R \cup \{u\}$.

Complexity = O(n) calls to CCW, thus $O(nd^3)$.

Examples

- ► Execution of FIND-OTHER-FACET(R, c) in ℝ², where ridge R is a vertex.
- Finding the first facet of the convex hull in \mathbb{R}^3 (lower hull).

Initialization: Searching for a Supporting Hyperplane

Equation of a hyperplane:

 $k_1x_1 + \dots + k_{d-1}x_{d-1} + k_dx_d + \lambda, \quad k_1, \dots, k_d, \lambda \in \mathbb{Q}.$ (8)

- Searching for a facet non-parallel to the x_d-axis, meaning the hyperplane intersects the axis: k_d ≠ 0.
- Can be written as:

$$x_d = k_1 x_1 + \dots + k_{d-1} x_{d-1} + \lambda, \quad k_1, \dots, k_{d-1}, \lambda \in \mathbb{Q}.$$
 (9)

Such a facet exists if the volume of the convex hull is > 0 in R^d.

Constraints of the Supporting Hyperplane

• Each input point $p_i = (p_{i1}, p_{i2}, ..., p_{id})$ must satisfy:

$$k_1 p_{i1} + k_2 p_{i2} + \dots + k_{d-1} p_{i(d-1)} + \lambda \le p_{id}.$$

 ・

Points satisfying equality lie on the facet; the rest are above it.

- If the convex hull is bounded, such a supporting facet defines the lower boundary.
- The hyperplane intersects the x_d-axis as high as possible by maximizing λ.

Exercise

Apply this initialization in two dimensions: which edge is computed?

Linear Program for Initializing Gift Wrapping

The first facet of the convex hull is found by solving the following linear program:

Linear Program

 $\begin{array}{ll} \text{Maximize} & \lambda \\ \text{subject to} & k_1p_{i1}+k_2p_{i2}+\dots+k_{d-1}p_{i,d-1}+\lambda \leq p_{i,d}, \quad \forall i=1,\dots,n. \\ & k_d=1. \end{array}$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Wrapping Algorithm for Convex Hull

general dimension

Input: *n* points in \mathbb{R}^d in general position. Output: Convex hull representation.

- 1. Compute and print an initial facet F.
- 2. Initialize the RACH structure with ridges $(F \{x\}, x)$ for all $x \in F$.
- 3. While RACH has elements:
 - Let $(R, c) \in \mathsf{RACH}$.
 - Compute and print $F \leftarrow \text{FIND-OTHER-FACET}(R, c)$.
 - For each vertex $x \in F$:
 - If a ridge $(F \{x\}, y)$ exists in RACH, delete it.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

• Otherwise, insert $(F - \{x\}, x)$ into RACH.

Complexity of Gift Wrapping Algorithm

- Initial facet: Solving a linear program with n constraints in d dimensions, cost O(n) [Megiddo].
- Initializing RACH = O(d).
- Wrapping:
 - Searching and adding ridges in RACH O(log n^{⌊d/2}⌋) = O(d log n).
 - Each FIND-OTHER-FACET call takes $O(nd^3)$.
 - ▶ In a simplicial polyhedron, there are O(d) points per facet \Rightarrow cost $O(d^2 \log n)$.
 - Total time complexity = $O(nHd^3)$, where *H* is the number of facets.

Is it output-sensitive?
