Vertex and Facet Representation of Polytopes Minkowski-Weyl

A polytope can be represented in two dual ways:

- 1. Vertex Representation (V-representation):
 - Describes a polytope as the convex hull of a finite set of vertices:

$$P = \operatorname{conv}\{v_1, v_2, \dots, v_n\}.$$
(1)

2. Facet Representation (H-representation):

Describes a polytope as the intersection of a finite number of half-spaces:

$$P = \{ x \in \mathbb{R}^d \mid Ax \le b \}.$$
(2)

- Convex hull problem: V-rep to H-rep
- Vertex enumeration problem: H-rep to V-rep
- Equivalent via duality

Polar Duality of Polytopes

▶ The **polar dual** of a polytope *P* is defined as:

$$P^* = \{ y \in \mathbb{R}^d \mid x \cdot y \le 1, \forall x \in P \}.$$
(3)

Key Properties:

- The dual of a convex polytope is also a convex polytope.
- The vertices of P correspond to the facets of P* and vice versa.
- If P is given in V-representation (vertices), P* is given in H-representation (half-spaces), and vice versa.

Numerical example I

The polytope P has the following vertices:

$$(-1,1), (2,1), (-1,-2), (0,-2), (2,0)$$

Defining inequalities:

$$0: x_1 \ge -1
1: x_2 \ge -2
2: -x_1 + x_2 \ge -2
3: -x_1 \ge -2
4: -x_2 \ge -1$$

The polar dual P^* has inequalities corresponding to the vertices of P, and vice versa.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Numerical example II

The dual polytope P^* has the following vertices:

$$(0,1), (-1,0), (0,-1/2), (1/2,-1/2), (1/2,0)$$

Defining inequalities of P^* (corresponding to the vertices of P):

$$\begin{array}{rrrr} 0: & -x_1+x_2 \geq -1 \\ 1: & 2x_1+x_2 \geq -1 \\ 2: & -x_1-2x_2 \geq -1 \\ 3: & -2x_2 \geq -1 \\ 4: & 2x_1 \geq -1 \end{array}$$

Examples of Polar Polytopes

1. The cube and the octahedron(cross-polytope) are polar duals.

(日) (四) (日) (日) (日)

2. What is the dual of the i) triangular prism, ii) simplex?

Fourier-Motzkin (FM) elimination

Topics:

From linear equalities (Gauss elim.) to linear inequalities (FM elim)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- Equivalence of representations (V-rep = H-rep)
- FM as a convex hull algorithm
- FM as an LP solver

Equivalence of Polytope Representations

A V-polytope is defined as:

$$x \in \mathbb{R}^d$$
, $x = \sum_{i=1}^n \lambda_i v_i + \sum_{i=1}^{n'} t_i r_i$, $t_i \ge 0$, $\lambda_i \ge 0$, $\sum_{i=1}^n \lambda_i = 1$

where $\{v_1, v_2, \ldots, v_n\}$ are the vertices and $\{r_1, r_2, \ldots, r_{n'}\}$ are the rays of the cone.

A H-polytope is defined by a set of halfspaces:

$$x \in \mathbb{R}^d$$
 : $\{Ax \le z\}, A \in \mathbb{R}^{m \times d}, z \in \mathbb{R}^m$

where A is a matrix of coefficients and z is a vector of bounds.

Fourier-Motzkin for convex hull computations

What is the representation of the following polytope?

$$(x,\lambda,t)\in\mathbb{R}^{d+n+n'}, x=\sum_{i=1}^n\lambda_iv_i+\sum_{i=1}^{n'}t_ir_i, \quad t_i\geq 0, \lambda_i\geq 0, \sum_{i=1}^n\lambda_i=1$$

Project in x coordinates, by eliminating λ , t.

What is the representation of the new "eliminated" polytope?

Reverse Search Method

[Avis, Fukuda]

- 1. Find an initial vertex using linear programming.
- 2. Define an adjacency structure where vertices represent polyhedral vertices.
- 3. Use reverse search to traverse the vertex graph efficiently.
- 4. Maintain only local information to reduce memory usage.

Complexity

- Time: O(VE) where V = vertices, E = edges.
- Space: O(d) (stores only one vertex at a time).

(a) The "simplex tree" induced by the objective $(-\sum x_i)$.

(b) The corresponding reverse search tree.

Output sensitive convex hull algorithms

A convex hull algorithm is total-polynomial it runs in time bounded by a polynomial in n, d, m (# input points, dimension, # output facets).

- Generic posotion: There are output sensitive algorithms (e.g. gift wrapping)
- Generic posotion: Reverse search algorithm is both output-senstive and compact (its space complexity is polynomial in the input size only)
- There is no known total-polynomial algorithm for the general (degenerate) case
