## Efficient and Equitable Taxation

gkaplanoglou, public finance

# Optimal Commodity Taxation

- Assume that the goal is to finance expenditures with a minimum of excess burden.
- Assume lump sum taxes are infeasible.
- 3 commodities:
  - Good X, Y, and leisure
  - Prices  $P_X$ ,  $P_Y$ , and  $w$ .

# Optimal Commodity Taxation

T- time endowment, l=leisure, t=tax rate

$$w(T - l) = P_X X + P_Y Y$$

$$wT = P_X X + P_Y Y + wl$$

$$wT = (1 + t)P_X X + (1 + t)P_Y Y + (1 + t)wl$$

$$\frac{1}{1 + t} wT = P_X X + P_Y Y + wl$$

# Optimal Commodity Taxation :

## Case 1 – All goods can be taxed

- In this case, the inability to impose a lump sum tax is irrelevant.
- The government can effectively take away a lump sum amount through equal taxes on all commodities (*including leisure*).
- **No excess burden.**

# Optimal Commodity Taxation:

## Case 2 – Not all goods can be taxed

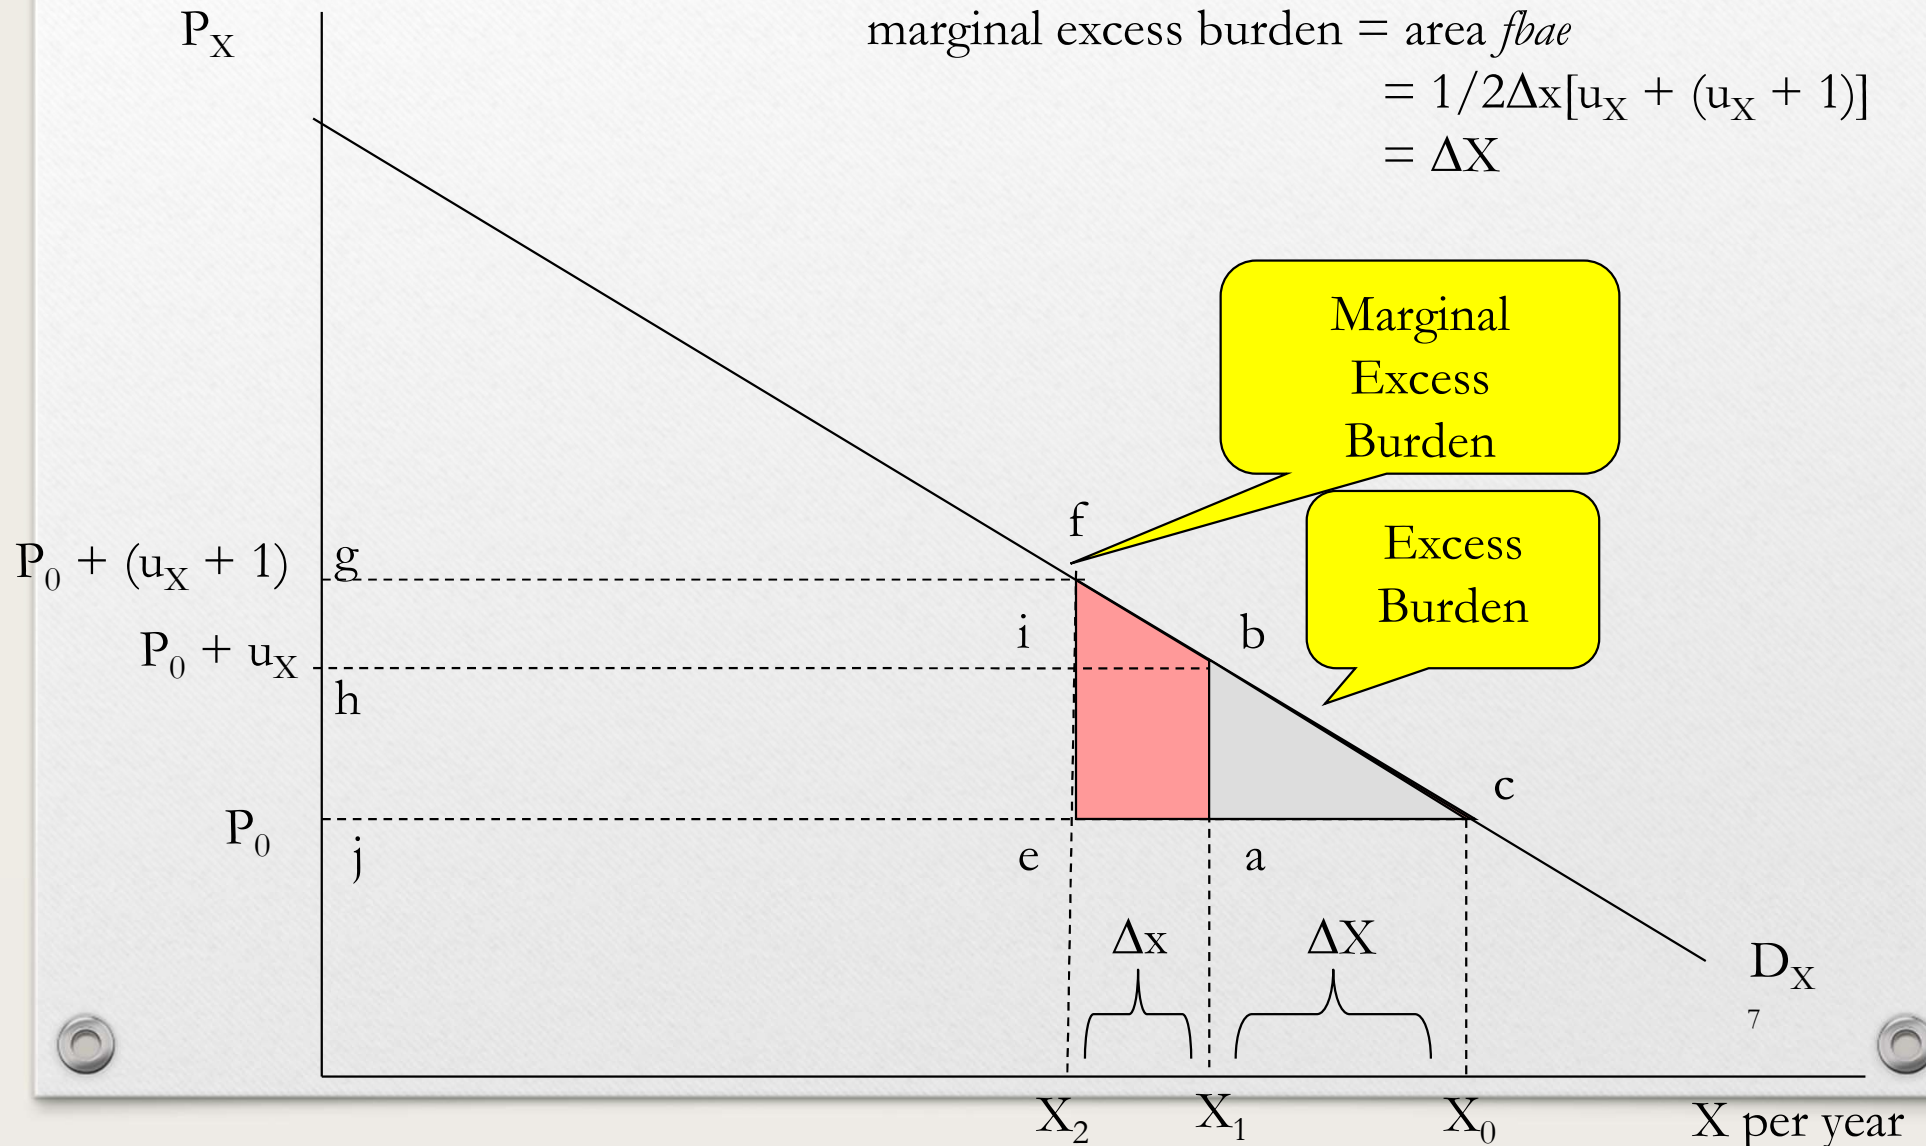

- May be impossible to tax non-market work.
- Assume only taxes can be applied to goods X and Y.
- In general, some excess burden is inevitable. Key question is how to select rates on X and Y to minimize excess burden subject to the revenue constraint.

# Optimal Commodity Taxation: Ramsey Rule

- Consider the idea of *marginal excess burden*
  - The additional inefficiency from incrementally raising a tax by a small amount.
  - Figure below shows the initial excess burden as a triangle ( $abc$ ), and the marginal excess burden as a trapezoid ( $fbae$ ).

# Optimal Commodity Taxation: Ramsey Rule

# Optimal Commodity Taxation: Ramsey Rule

$$\begin{aligned}\text{change in tax revenues} &= \text{area } gfi h - \text{area } ibae \\ &= X_2 - (X_1 - X_2)u_X\end{aligned}$$

$$\text{marginal tax revenue} = X_1 - \Delta X$$

$$\begin{aligned}\text{marginal tax revenue per additional dollar of tax revenue} \\ &= \Delta X / (X_1 - \Delta X)\end{aligned}$$

$$\begin{aligned}\text{marginal tax revenue per additional dollar of tax revenue for good } Y \\ &= \Delta Y / (Y_1 - \Delta Y)\end{aligned}$$

$$\begin{aligned}\text{To minimize overall excess burden} \\ &= \Delta X / (X_1 - \Delta X) = \Delta Y / (Y_1 - \Delta Y)\end{aligned}$$

$$\frac{\Delta X}{X_1} = \frac{\Delta Y}{Y_1} \text{ therefore}$$

# Optimal Commodity Taxation: Ramsey Rule

- Similar reasoning is used for good Y.
- Optimization therefore leads to:

$$\frac{\Delta X}{X_1} = \frac{\Delta Y}{Y_1}$$

- Ramsey rule says that to minimize total excess burden, tax rates should be set so the percentage reduction in the quantity of each good demanded is the same.

# Optimal Commodity Taxation: Ramsey Rule reinterpreted

- Recall the formula for excess burden for good X:

$$EB_X = \frac{1}{2} |\eta| P_X X t_X^2$$

- Planner's optimization problem is to minimize total excess burden by choose taxes on goods X and Y, subject to a revenue constraint.

# Optimal Commodity Taxation: Ramsey Rule reinterpreted

- Setting up the Lagrangian:

$$\min_{t_X, t_Y, \lambda} L = \frac{1}{2} |\eta_X| P_X X t_X^2 + \frac{1}{2} |\eta_Y| P_Y Y t_Y^2 + \lambda (R - P_X X t_X - P_Y Y t_Y)$$

# Optimal Commodity Taxation: Ramsey Rule reinterpreted

- Solving leads to a relationship between tax rates and elasticities:

$$t_X \eta_X = t_Y \eta_Y$$

- Or rearranging we have the *inverse elasticity rule*:

$$\frac{t_X}{t_Y} = \frac{\eta_Y}{\eta_X}$$

# Optimal Commodity Taxation: Ramsey Rule reinterpreted

- Implication of the inverse elasticity rule:
  - As long as goods are unrelated in consumption (neither complements nor substitutes), tax rates should be inversely proportional to elasticities.
  - When good Y is relatively inelastic, tax it more.

# Optimal Commodity Taxation: Equity Considerations

- Is it “fair” to tax inelastic goods like food and medicine?
  - Clearly it is not.
- Another criteria for a tax system is *vertical equity*: it should distribute burdens fairly across people with different abilities to pay.

# Optimal Commodity Taxation: Equity Considerations

- Ramsey rule has been modified to account for the distributional issues.
- Degree of departure from original rule depends on:
  - How much society cares about equity
  - Extent to which consumption patterns of rich and poor differ

# Optimal User Fees

- If government produces a good or service, must directly choose a *user fee*.
  - A *user fee* is price paid by users of the good or service to the government.
  - For example, *natural monopoly*.
- What is the “best” fee?

# Optimal User Fees

- Consider the natural monopoly in Figure 14.2.
  - Continually decreasing average costs
  - Marginal cost lies everywhere below average cost

# Optimal User Fees

A Natural Monopoly

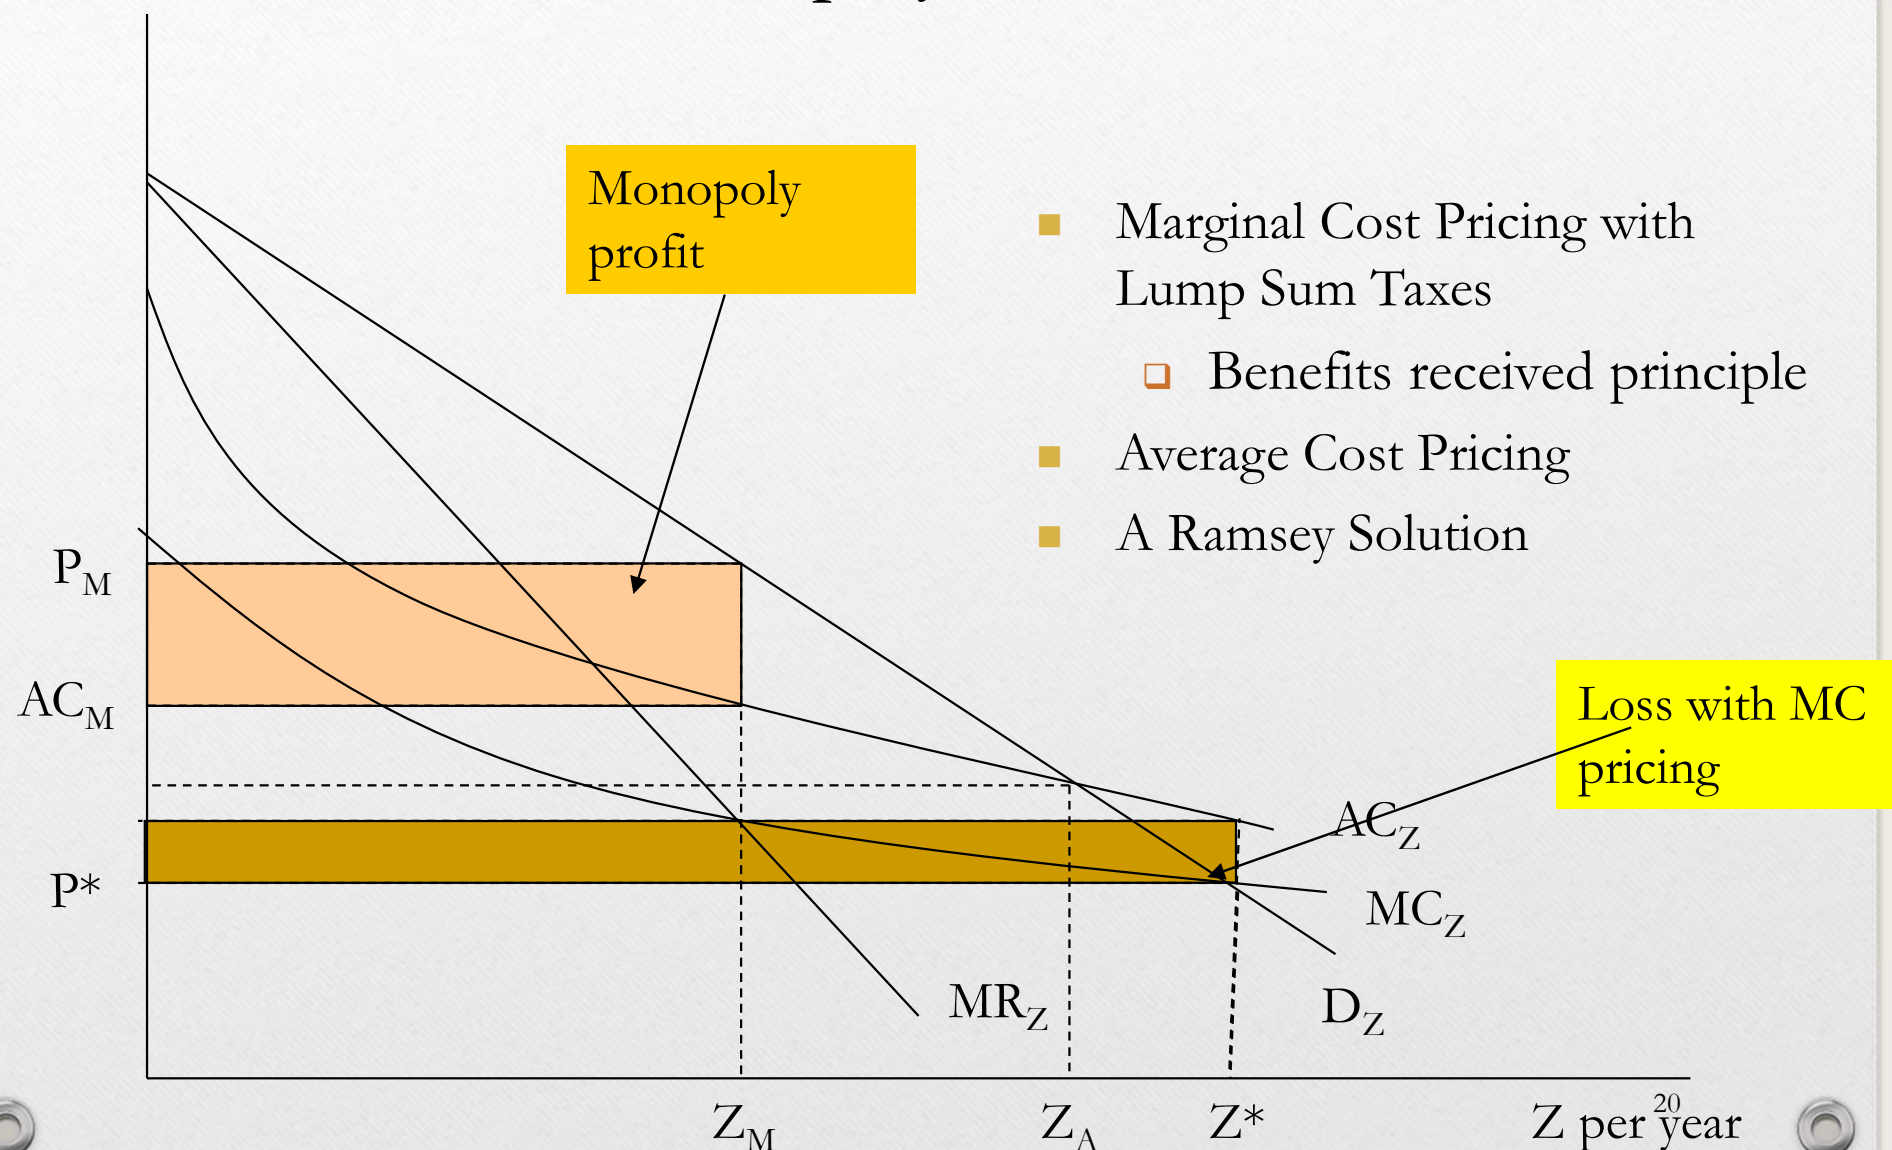

# Optimal User Fees

- A private firm would set  $MR=MC$ , and choose  $Z_m$ . This output level leads to inefficiency.
- See Figure below

# Optimal User Fees

## A Natural Monopoly

# Optimal User Fees

- Efficiency would require  $P=MC$ , or output at  $Z^*$ .
- Key problem is that at this quantity, price is less than average cost, so the operation suffers losses.

# Optimal User Fees

- Policy solutions:
  - *Average cost pricing*: Zero profits, but  $Z_A < Z^*$ .
  - *Marginal cost pricing with Lump Sum Taxes*: Set  $P=MC$ , provide  $Z^*$  at a loss, and finance it with a lump sum tax.
    - Assumes such a tax is available
    - Equity considerations – who uses the good?

# Optimal User Fees

- Second principle is called the *benefits-received principle* – consumers of a publicly provided service pay for it.
- A Ramsey Solution
  - If government is running several enterprises, choose markup over marginal costs subject to a breakeven constraint.

# Optimal Income Taxation

- $W = U_1 + U_2 + \dots + U_n$
- Individuals have identical utility functions that depend only on their incomes
- Total amount of income fixed
- Implications of model for income tax

# Optimal Income Taxation

- Edgeworth's model implies a radically progressive tax structure: marginal tax rates on high income individuals are 100%.
- Key problem is work incentives are not accounted for.

# Other Criteria for Tax Design

- Horizontal equity: People in equal positions should be treated equally
  - Measures represent outcomes of people's decisions so it is difficult to figure out whether they were initially in equal position.
- Costs of running a tax system
  - Tax *evasion*
  - Tax *avoidance*

# Tax Evasion

- *Tax evasion* is failing to pay legally due taxes.
- Tax cheating difficult to measure, and probably manifests itself in a number of ways:
  - Keeping two sets of books
  - Moonlighting for cash
  - Barter
  - Deal in cash

# Tax Evasion

- Suppose person cares only about maximizing expected income
  - Goal is to choose  $R$ , the amount that is hidden from authorities
  - Marginal benefit of hiding income is the tax rate
- Assume authorities randomly audit with probability  $q$ , and increasing penalty for greater amounts hidden.

# Tax Evasion

- Figure below shows that optimal underreporting occurs when the expected marginal benefit from doing so exceeds the marginal cost.
  - Implications: Cheating increases with tax rates and decreases with enforcement.

# Tax Evasion

$MC = \varrho * \text{marginal}$   
penalty

$MB = t$

$R^*$

(Euros of  
underreporting)

$MC = \varrho * \text{marginal}$   
penalty

$MB = t$

$R^* = 0$

(Euros of underreporting)

# Tax Evasion

- Ignores a number of real-world aspects:
  - Psychic costs of cheating
  - Risk aversion
  - Work choices
  - Probabilities of audit

Figure 1: Consolidated Global Profits vs. Observable Profits Across Subsidiaries

Notes: This graph shows the difference between Apple's, Facebook's, Alphabet's, and Nike's global consolidated profits, and the sum of the profits made by Apple's, Facebook's, Alphabet's, and Nike's subsidiaries, as recorded in Orbis. The difference is due to the fact that the subsidiaries where these firms make the bulk of their profits are not visible in Orbis. Source: authors' computations using Orbis data.

# Zucman et al (2024) Global Tax Evasion Report

## Ugly news – Billionaires often avoid the income tax often by holding companies

**Figure 4**

The tax deficit of billionaires

**Notes:** This figure reports estimates of effective tax rates by pre-tax income groups and for billionaires in France, the Netherlands, and the United States. These estimates include all taxes paid at all levels of government and are expressed as a percent of pre-tax income. P0-10 denotes the 10% of adults at the bottom of the pre-tax income distribution, P10-20 the next decile, etc. Pre-tax income includes all national income (measured following standard national account definitions) before government taxes and transfers and after the operation of the pension system. National income excludes unrealized capital gains but includes the retained earnings of companies. Sources: see chapter 4.

# Recap of Efficient and Equitable Taxation

---

- Optimal Commodity Taxation
  - All goods taxed
  - Only some taxed
- User fees
- Tax Evasion
